

*A Longitudinal Study of Human Energy Field in Infants and Young Children*

By Jean A. Metzker

2000

Abstract

The purpose of this study was to observe human energy fields (HEF) in infants and young children for a two-year time span. There was a strong relationship between the amount of density, amount of light, and width of the field, while the sample is not large, the study begins to establish an empirical basis for change in the energy fields of children as they grow and develop.
